A Courant algebroid over a manifold M is a vector bundle $C \rightarrow M$ with a fibrewise nondegenerate symmetric bilinear form $\langle \cdot, \cdot \rangle$, a bracket $[[\cdot, \cdot]]$ on the smooth sections $\Gamma(C)$, and an anchor $\rho: C \rightarrow TM$, which satisfy the following conditions

- 1 $[[c_1, [[c_2, c_3]]] = [[[c_1, c_2]], c_3] + [[c_2, [[c_1, c_3]]]$,
- 2 $\rho(c_1)\langle c_2, c_3 \rangle = \langle [[c_1, c_2]], c_3 \rangle + \langle c_2, [[c_1, c_3]] \rangle$,
- 3 $[[c_1, c_2]] + [[c_2, c_1]] = \rho^*\mathbf{d}\langle c_1, c_2 \rangle$

for all $c_1, c_2, c_3 \in \Gamma(C)$.

useful?

The best understood example of a Courant algebroid is the following.

Let M be a smooth manifold. Then the direct sum $TM \oplus T^*M$ over M , with

- 1 the anchor $\rho := \text{pr}_{TM} : TM \oplus T^*M \rightarrow TM$,
- 2 the pairing

$$\langle (X_1, \theta_1), (X_2, \theta_2) \rangle = \theta_2(X_1) + \theta_1(X_2),$$

- 3 and the bracket

$$[[X_1, \theta_1], [X_2, \theta_2]] = ([X_1, X_2], \mathcal{L}_{X_1}\theta_2 - \mathbf{i}_{X_2}\mathbf{d}\theta_1)$$

is a Courant algebroid.

Why is that
useful?

A *Dirac structure* on M is a subbundle $D \subseteq TM \oplus T^*M$ with $D = D^\perp$ relative to the pairing and $[[\Gamma(D), \Gamma(D)]] \subseteq \Gamma(D)$.

In particular, given a vector bundle $q: E \rightarrow M$, the space $TE \oplus T^*E \rightarrow E$ carries the standard Courant algebroid structure.

In fact, this Courant algebroid structure is *linear*. The space $TE \oplus T^*E$ is a double vector bundle

$$\begin{array}{ccc}
 TE \oplus T^*E & \longrightarrow & E \\
 \downarrow & & \downarrow \\
 TM \oplus E^* & \longrightarrow & M
 \end{array}$$

VB-Courant
algebroids

Why is that
useful?

Given a Dorfman connection

$$\Delta: \Gamma(TM \oplus E^*) \times \Gamma(E \oplus T^*M) \rightarrow \Gamma(E \oplus T^*M),$$

$$\nabla: \Gamma(TM \oplus E^*) \times \Gamma(E) \rightarrow \Gamma(E) \quad \nabla_v e = \text{pr}_E(\Delta_v(e, 0))$$

defines a linear connection.

- 4 Why is that useful?

Theorem (Li-Bland 2012, J.L.2015)

The category of Lie 2-algebroids is equivalent to the category of VB-Courant algebroids.

Splittings of a Lie 2-algebroid correspond to maximally isotropic linear splittings of the corresponding VB-Courant algebroid.

$$\begin{array}{ccc} E & \longrightarrow & B \\ \downarrow & & \downarrow \\ Q & \longrightarrow & M \end{array}$$

A split Lie 2-algebroid $Q \oplus B^* \rightarrow M$ is a pair of an anchored vector bundle $(Q \rightarrow M, \rho_Q)$ and a vector bundle $B \rightarrow M$, together with

- 1 a vector bundle map $\partial_B^* : B^* \rightarrow Q$,
- 2 a skew-symmetric dull bracket $[[\cdot, \cdot]] : \Gamma(Q) \times \Gamma(Q) \rightarrow \Gamma(Q)$,
- 3 a linear connection $\nabla^* : \Gamma(Q) \times \Gamma(B^*) \rightarrow \Gamma(B^*)$ and
- 4 a vector valued 3-form $\omega \in \Omega^3(Q, B^*)$,

such that

- (i) $\nabla_{\partial_B^*(\beta_1)}^* \beta_2 + \nabla_{\partial_B^*(\beta_2)}^* \beta_1 = 0$,
- (ii) $[[q, \partial_B^*(\beta)]] = \partial_B^*(\nabla_q^* \beta)$,
- (iii) $\text{Jac}_{[[\cdot, \cdot]]} = -\partial_B^* \circ \omega \in \Omega^3(Q, Q)$,
- (iv) $R_{\nabla^*}(q_1, q_2)\beta = \omega(q_1, q_2, \partial_B^*(\beta))$, and
- (v) $\mathbf{d}_{\nabla^*} \omega = 0$

for all $\beta, \beta_1, \beta_2 \in \Gamma(B^*)$ and $q, q_1, q_2 \in \Gamma(Q)$.

Let E be a vector bundle over M , choose a *skew-symmetric* dull bracket $[[\cdot, \cdot]]$ on $TM \oplus E^*$ and let Δ be the dual Dorfman connection.

Then $\text{pr}_E^* : E^* \hookrightarrow TM \oplus E^*$, $\nabla = \text{pr}_E \circ \Delta \circ \iota_E$, $[[\cdot, \cdot]]$ and

$$\omega \in \Omega^3(TM \oplus E^*, E^*), \quad \omega(v_1, v_2, v_3) = R_\Delta(v_1, v_2)^* v_3,$$

defines a split Lie-2-algebroid $(TM \oplus E^*) \oplus E^*$.

Let E be a vector bundle over M , choose a *skew-symmetric* dull bracket $[[\cdot, \cdot]]$ on $TM \oplus E^*$ and let Δ be the dual Dorfman connection.

Then $\text{pr}_E^* : E^* \hookrightarrow TM \oplus E^*$, $\nabla = \text{pr}_E \circ \Delta \circ \iota_E$, $[[\cdot, \cdot]]$ and

$$\omega \in \Omega^3(TM \oplus E^*, E^*), \quad \omega(v_1, v_2, v_3) = R_\Delta(v_1, v_2)^* v_3,$$

defines a split Lie-2-algebroid $(TM \oplus E^*) \oplus E^*$.
